Advances in Deep Learning with Applications in Text and Image Processing

- Word Embedding -

Prof. Matteo Matteucci – *matteo.matteucci@polimi.it*

Department of Electronics, Information and Bioengineering
Artificial Intelligence and Robotics Lab - Politecnico di Milano

Recall Machine Learning Paradigms

Immagine you have a certain experience E, i.e., a dataset, and let's name it

$$D = x_1, x_2, x_3, \dots, x_N$$

- ***Supervised Learnig***: given the desired outputs $t_1, t_2, t_3, \dots, t_N$ learn to produce the correct output given a new set of input
- ***Unsupervised learning***: exploit regularities in D to build a representation to be used for reasoning or prediction
- ***Reinforcement learning***: producing actions $a_1, a_2, a_3, \dots, a_$ whi… the environment, and receiving rewards $r_1, r_2, r_3, \dots, r_N$ le… to maximize rewards in the long term

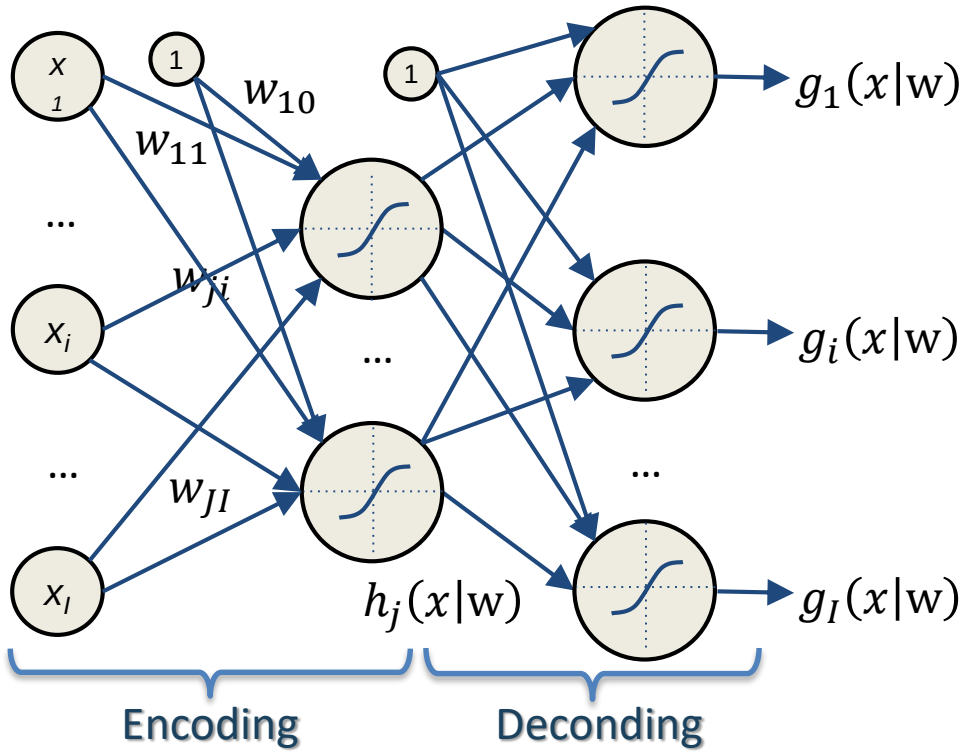
Haven't seen much of it, is it?

This course focuses mainly on Supervised and Unsupervised Learning …

Neural Autoencoder

Network trained to output the input (i.e., to learn the identity function)

- Limited number of units in hidden layers (compressed representation)
- Constrain the representation to be sparse (sparse representation)



$$x \in \Re^I \overset{enc}{\longrightarrow} h \in \Re^J \overset{dec}{\longrightarrow} g \in \Re^I$$
$$I << J$$

$$E = \underbrace{\|g_i(x_i|w) - x_i\|^2}_{\text{Reconstruction error}} + \underbrace{\lambda \sum_j \left| h_j \left(\sum_i w_{ji}^{(1)} x_i \right) \right|}_{\text{Sparsity term}}$$

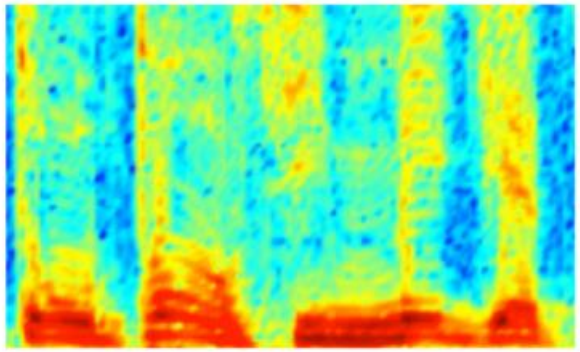
$$g_i(x_i|w) \sim x_i \qquad h_j(x_i|w) \sim 0$$

Word Embedding Motivation

Natural language processing systems treat words as discrete atomic symbols

- 'cat' is encoded as Id537
- 'dog' is encoded as Id143
- …

Items in a dictionary …



Audio Spectrogram

DENSE

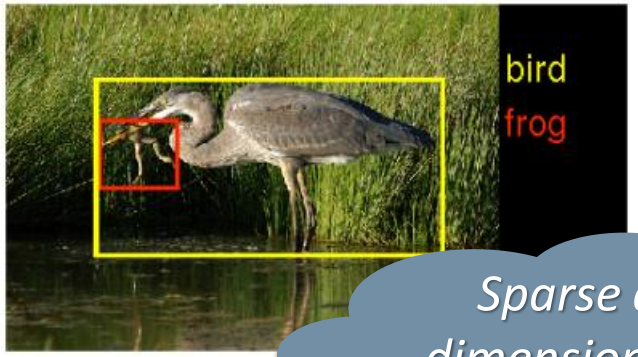


Image pixels

DENSE

A document becomes a Bag of Words

0	0	0	0.2	0	0.7	0	0	0	…	…

Sparse and high dimensional -> Curse of Dimensionality!

Word, context, or document vectors

SPARSE

Encoding Text is a Serious Thing

Performance of real-world applications (e.g., chatbot, document classifiers, information retrieval systems) depends on input encoding and several have been proposed:

Local representations

- N-grams
- Bag-of-words
- 1-of-N coding

Language Model →

Continuous representations

- Latent Semantic Analysis
- Latent Dirichlet Allocation
- Distributed Representations

Determine $P(s = w_1, \dots, w_k)$ in some domain of interest

$$P(s_k) = \prod_i^k P(w_i | w_1, \dots, w_{i-1})$$

In traditional n-gram language models "the probability of a word depends only on the context of n−1 previous words"

$$\hat{P}(s_k) = \prod_i^k P(w_i | w_{i-n+1}, \dots, w_{i-1})$$

Typical ML-smoothing learning process (e.g., Katz 1987):

- compute $\hat{P}(w_i | w_{i-n+1}, \dots, w_{i-1}) = \frac{\#w_{i-n+1}, \dots, w_{i-1}, w_i}{\#w_{i-n+1}, \dots, w_{i-1}}$
- smooth to avoid zero probabilities

N-gram Language Model: Curse of Dimensionality

Let's assume you train a 10-gram LM on a corpus of 100.000 unique words

- The model lives in a 10D hypercube where each dimension has 100.000 slots
- Model training ↔ assigning a probability to each of the 100.000^{10} slots
- *Probability mass vanishes* → more data is needed to fill the huge space
- The more data, the more unique words! → Is not going to work …

In practice:

- Corpuses can have 10^6 unique words
- Contexts are typically limited to size 2 (trigram model), e.g., famous Katz (1987) smoothed trigram model
- With short context length a lot of information is not captured

N-gram Language Model: Word Similarity Ignorance

Let assume we observe the following similar sentences

- *Obama speaks to the media in Illinois*
- *The President addresses the press in Chicago*

With classic one-hot vector space representations

- speaks = [0 0 1 0 … 0 0 0 0]
- addresses = [0 0 0 0 … 0 0 1 0]

speaks ⊥ addresses

- obama = [0 0 0 0 … 0 1 0 0]
- president = [0 0 0 1 … 0 0 0 0]

obama ⊥ president

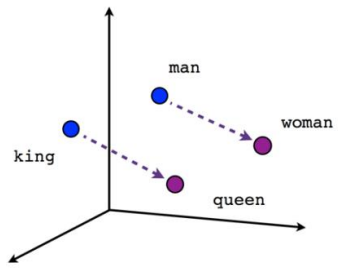
- illinois = [1 0 0 0 … 0 0 0 0]
- chicago = [0 1 0 0 … 0 0 0 0]

illinois ⊥ chicago

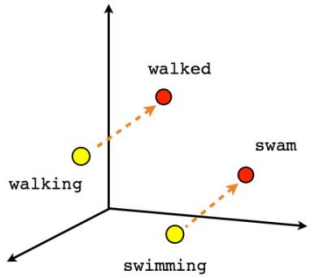
In each case, word pairs share no similarity, and we need word similarity to generalize

Embedding

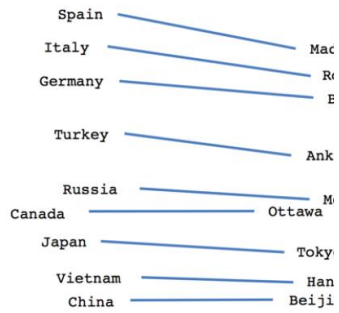
Any technique mapping a word (or phrase) from it's original high-dimensional input space (the body of all words) to a lower-dimensional numerical vector space - so one *embeds* the word in a different space



Male-Female



Verb tense



Country-Capital

Closer points are closer in meaning and they form clusters …

Word Embedding: Distributed Representation

Each unique word w in a vocabulary V (typically $\|V\| > 10^6$) is mapped to a point in a real continuous m-dimensional space (typically $100 < m < 500$)

$$w \in V \xrightarrow{mapping\ C} \Re^m$$

w_1 obama w_V

obama = [0 0 ... 0 1 0 ... 0 0] ⇒ obama = [0.12 ... -0.25]

«one-hot» encoding — feature vector (f_1 ... f_m)

Fighting the curse of dimensionality with:

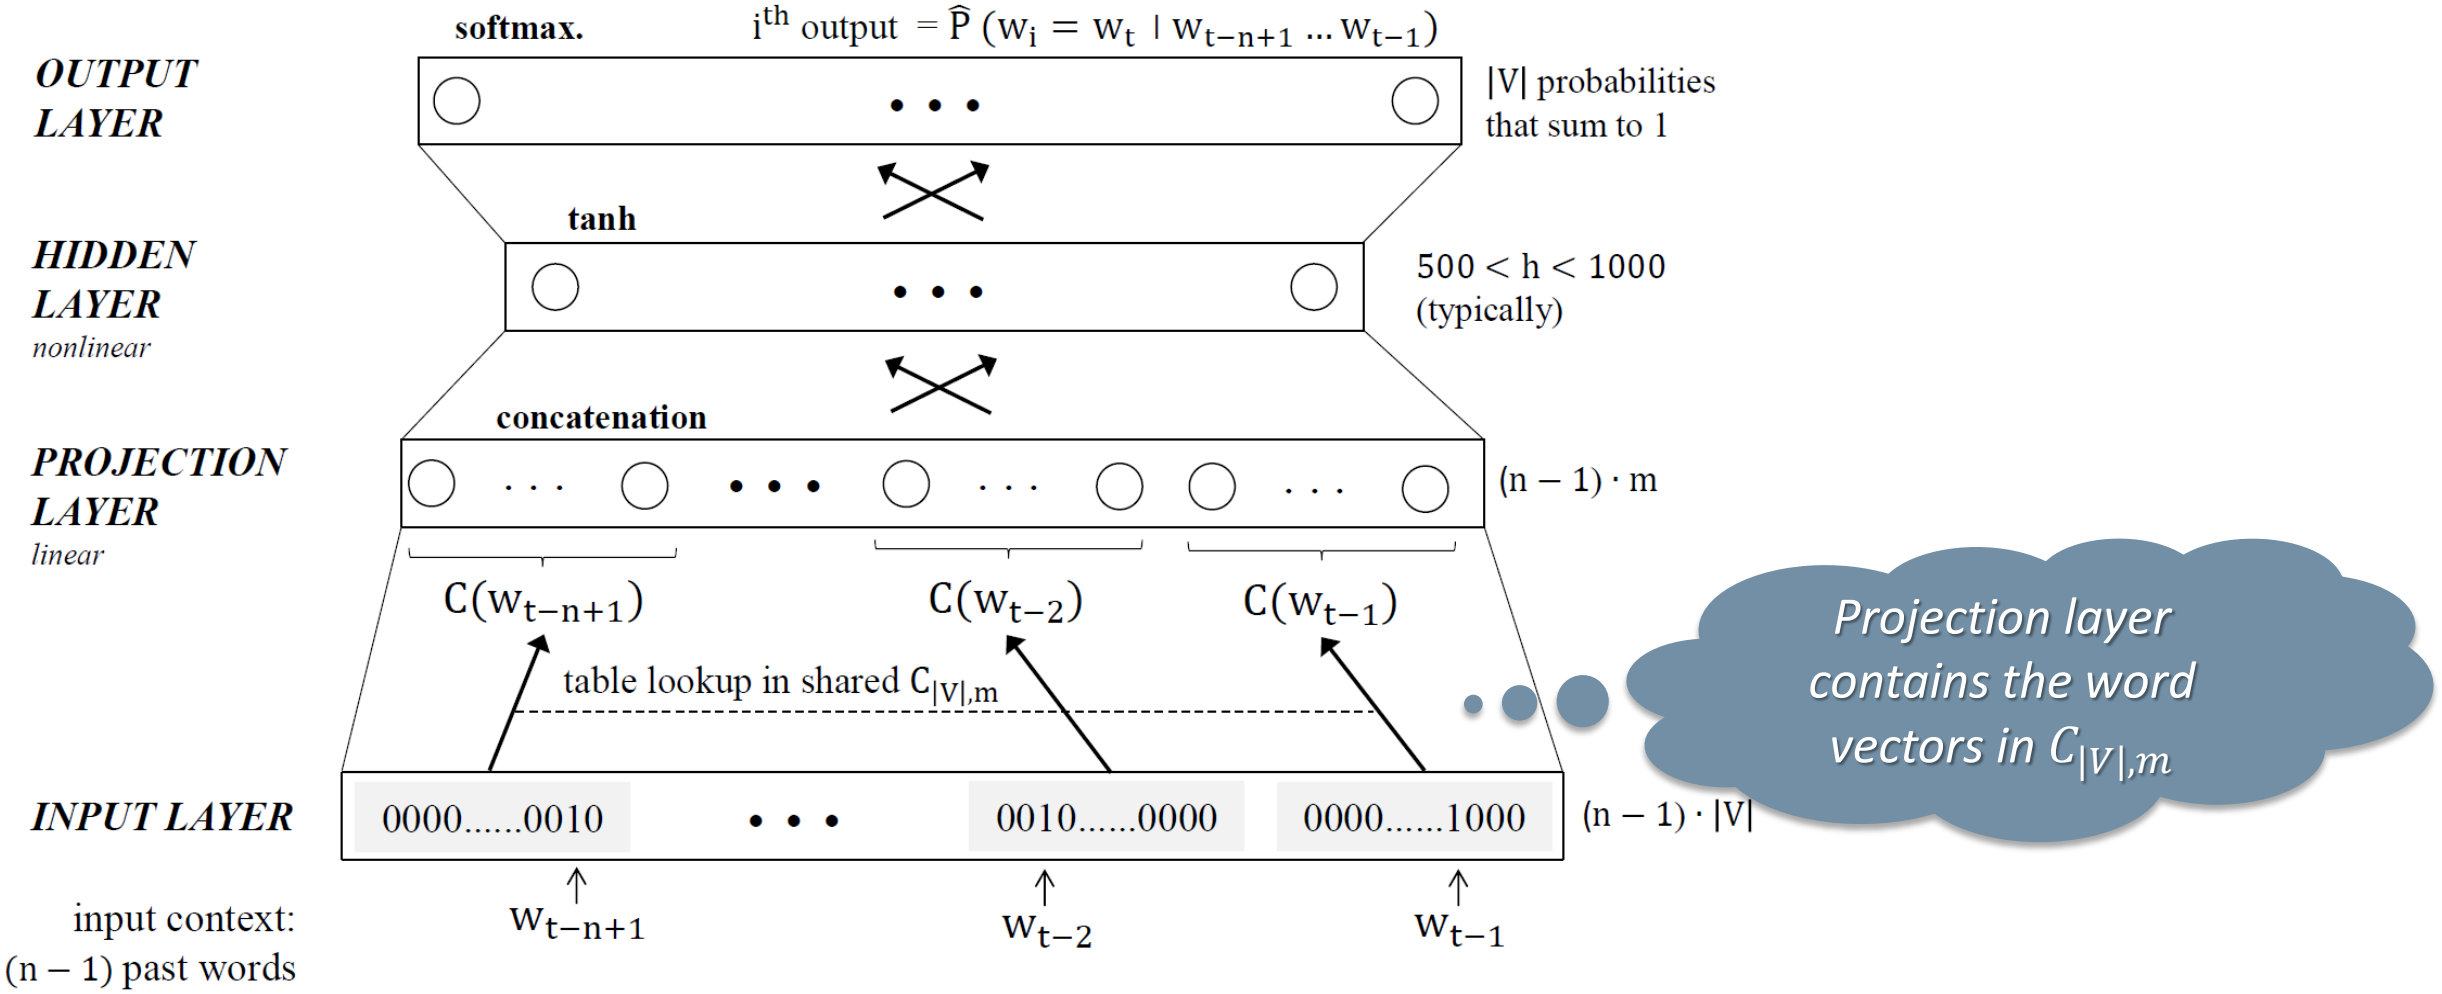
- Compression *(dimensionality reduction)*
- Smoothing *(discrete to continuous)*
- Densification *(sparse to dense)*

Similar words should end up to be close to each other in the feature space …

Neural Net Language Model (Bengio et al. 2003)

For each training sequence: input = (context, target) pair: $(w_{t-n+1} \ldots w_{t-1}, w_t)$

objective: minimize $E = -\log \hat{P}(w_t \mid w_{t-n+1} \ldots w_{t-1})$

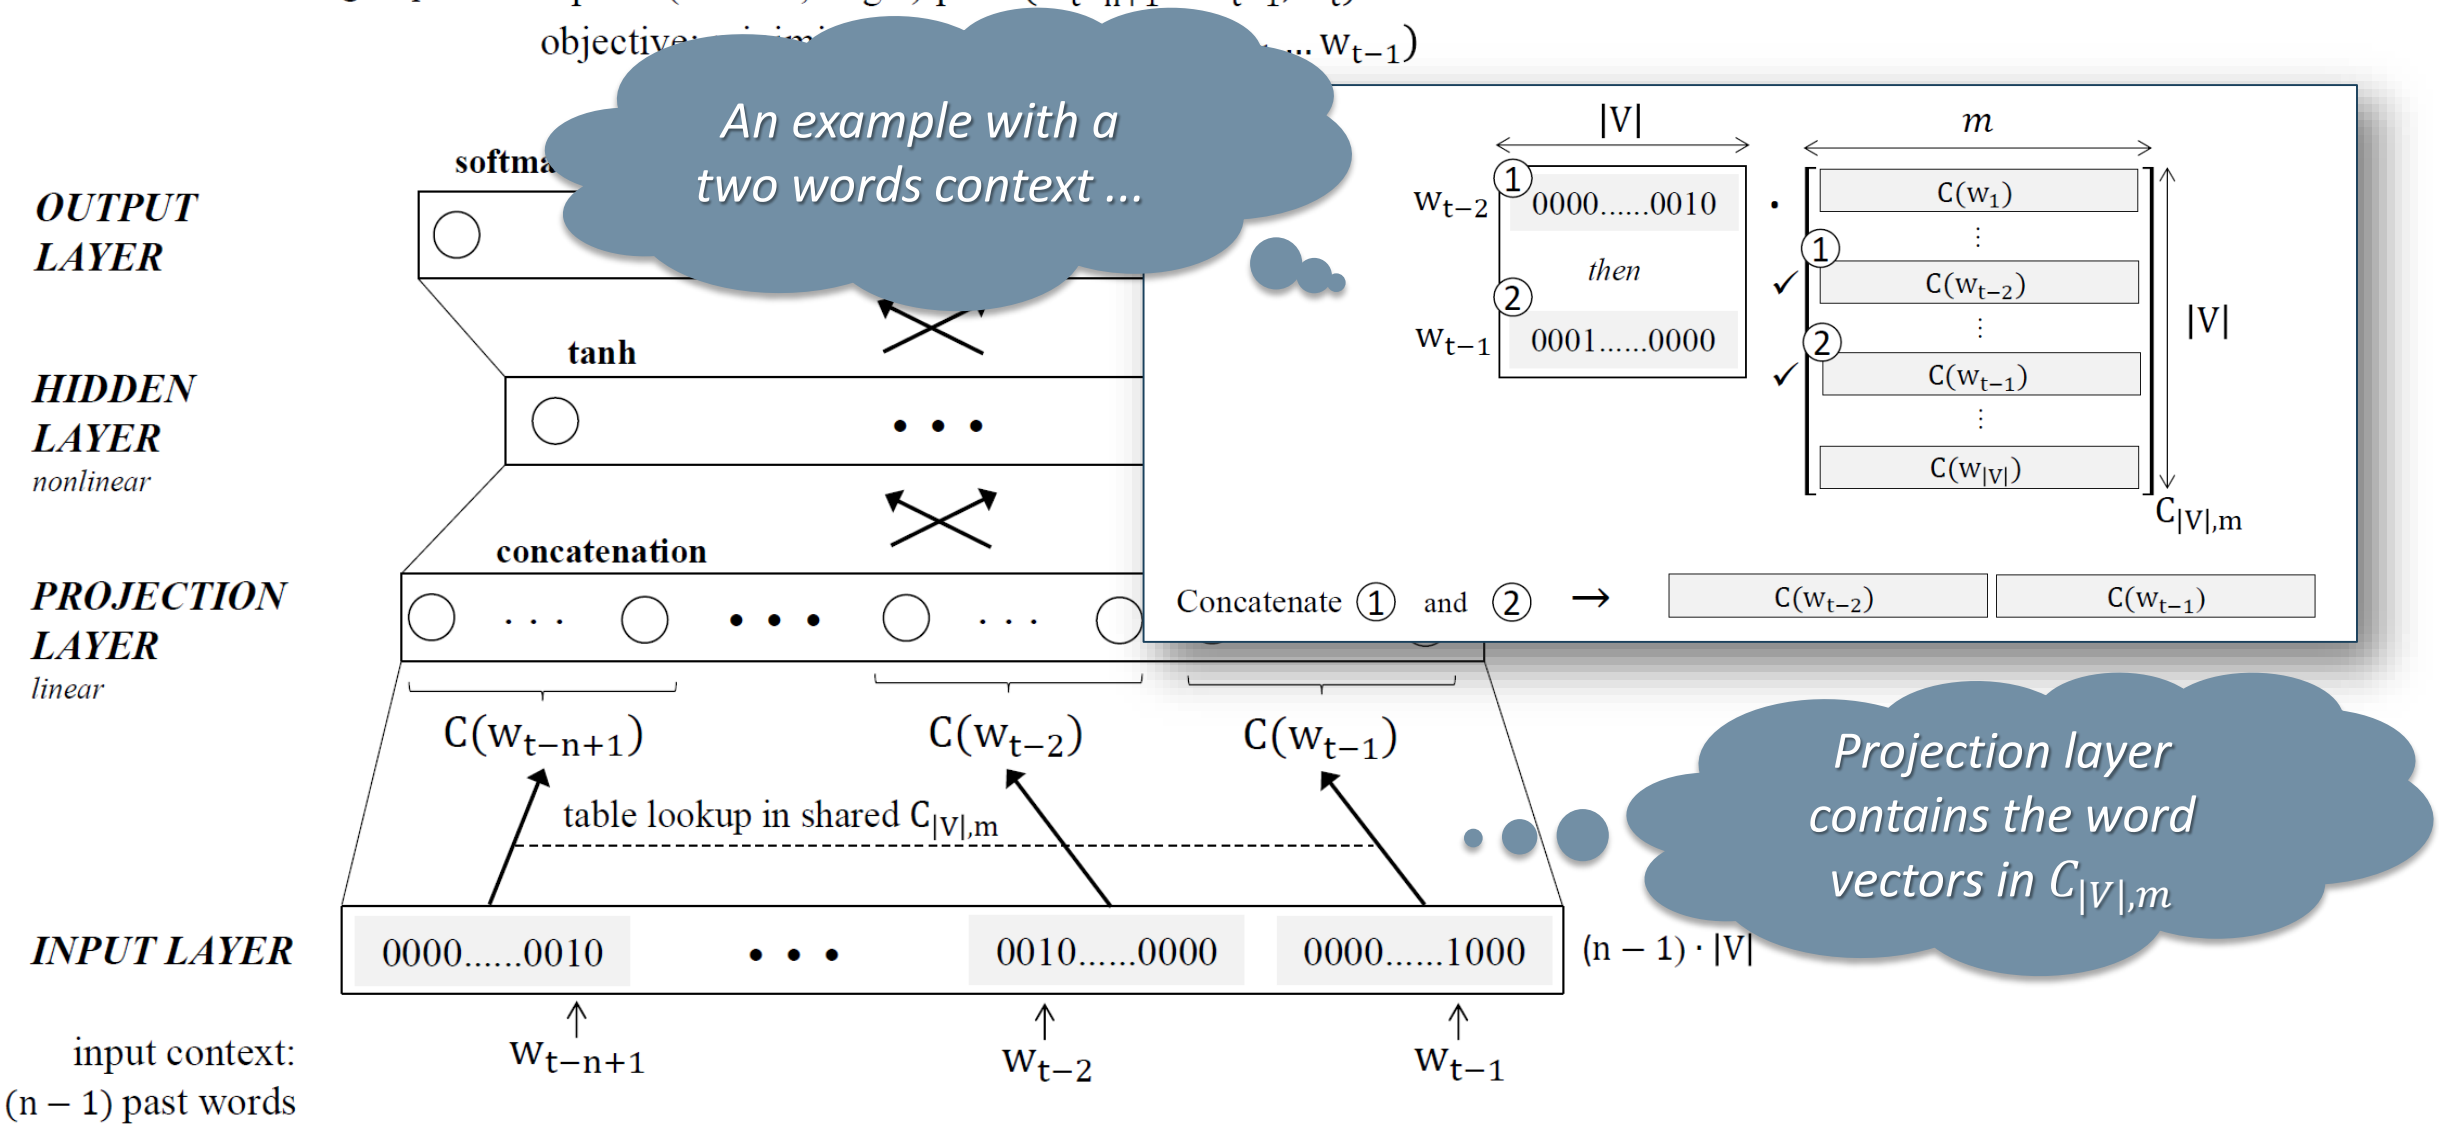


Projection layer contains the word vectors in $C_{|V|,m}$

Neural Net Language Model (Bengio et al. 2003)

For each training sequence: input = (context, target) pair: $(w_{t-n+1} \dots w_{t-1}, w_t)$

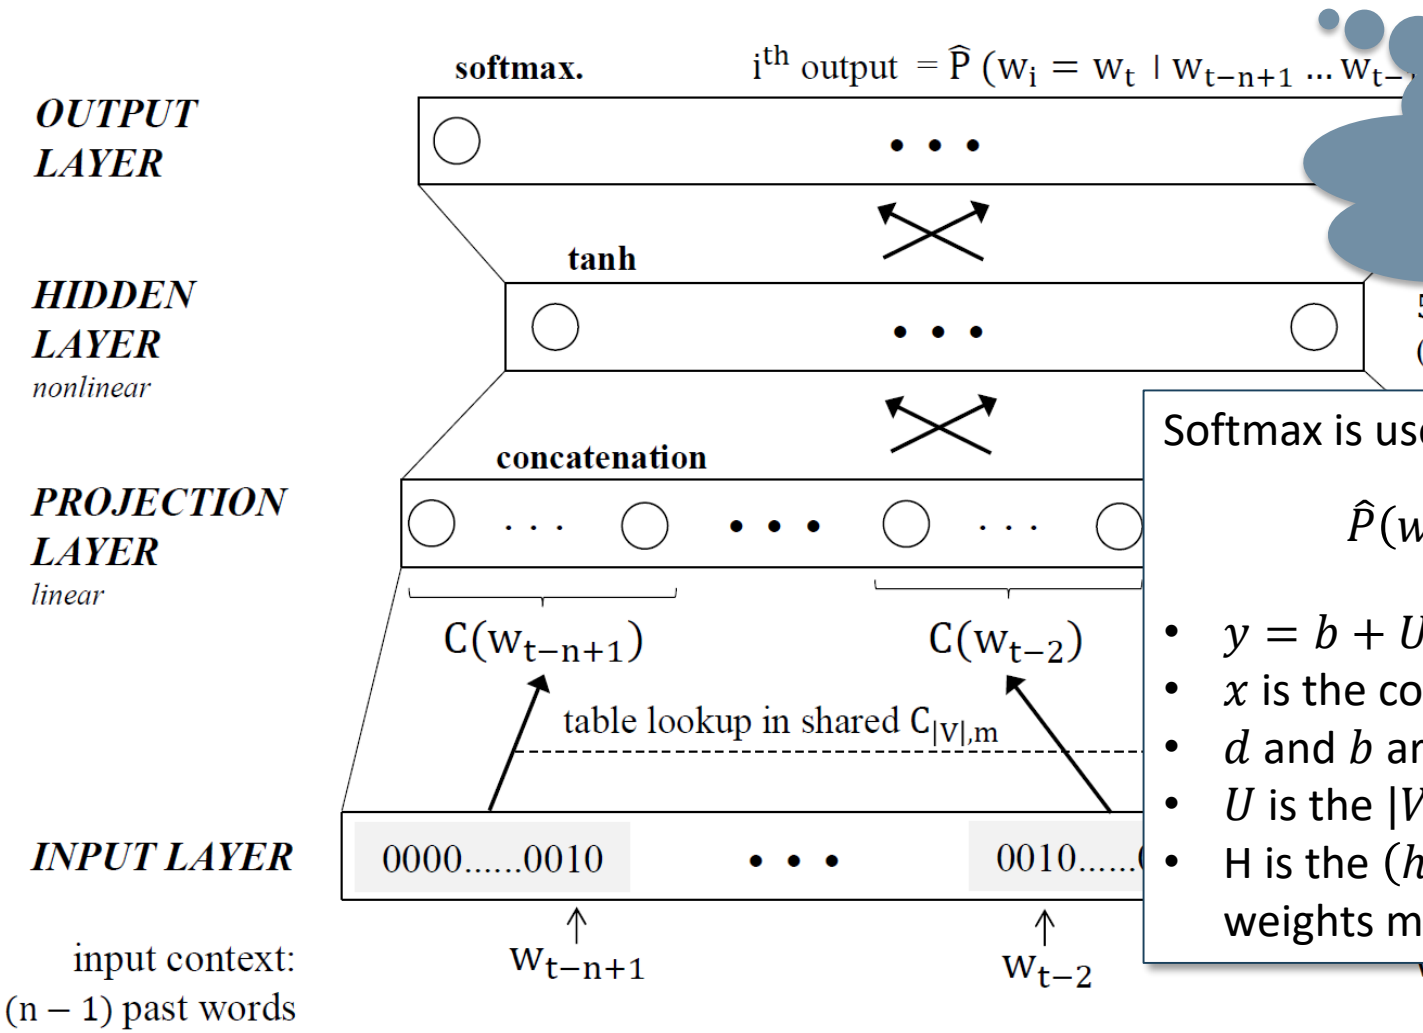
objective: ... $w_{t-1})$



Neural Net Language Model (Bengio et al. 2003)

For each training sequence: input = (context, target) pair: $(w_{t-n+1} \dots w_{t-1}, w_t)$

objective: minimize $E = -\log \hat{P}(w_t \mid w_{t-n+1} \dots w_{t-1})$



Training by stochastic gradient descent has complexity

$$n \times m + n \times m \times h + \boldsymbol{h} \times |\boldsymbol{V}|$$

Softmax is used to output a multinomial distribution

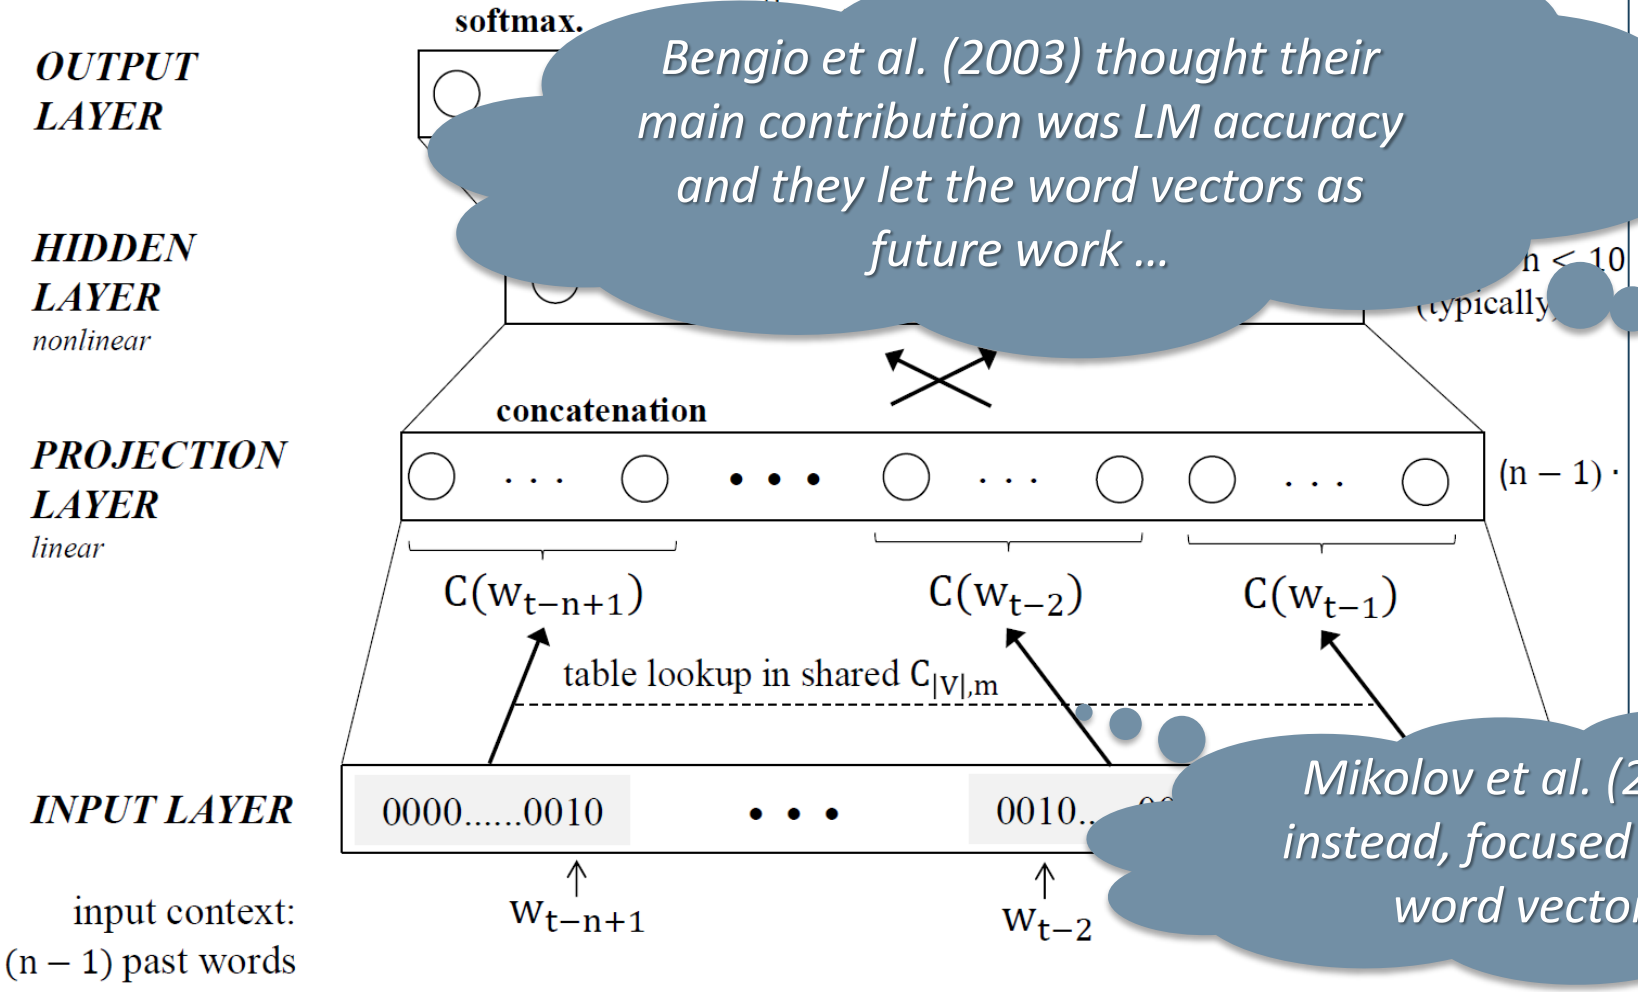
$$\hat{P}(w_i = w_t \mid w_{t-n+1}, \dots, w_{t-1}) = \frac{e^{y_{w_i}}}{\sum_{i'}^{|V|} e^{y_{w_{i'}}}}$$

- $y = b + U \cdot \tanh(d + H \cdot x)$
- x is the concatenation $C(w)$ of the context weight vectors
- d and b are biases (respectively h and $|V|$ elements)
- U is the $|V| \times h$ matrix with hidden-to-output weights
- H is the $(h \times (n-1) \cdot m)$ projection-to-hidden weights matrix

Neural Net Language Model (Bengio et al. 2003)

For each training sequence: input = (context, target) pair: $(w_{t-n+1} \dots w_{t-1}, w_t)$

objective: minimize $E = -\log \hat{P}(w_t \mid w_{t-n+1} \dots w_{t-1})$



Bengio et al. (2003) thought their main contribution was LM accuracy and they let the word vectors as future work …

Tested on Brown (1.2M words, V≅ 16K, 200K test set) and AP News (14M words, V≅ 150K reduced to 18K, 1M test set)

Brown: h=100, n=5, m=30
AP News: h=60, n=6, m=100

- **3 week** training using **40 cores**
- 24% (Brown) and 8% (AP News) relative improvement wrt traditional smoothed n-gram in terms of test set perplexity

Due to **complexity**, NNLM can't be applied to large data sets and it shows …nce on rare words

Mikolov et al. (2013), instead, focused on the word vectors

Google's word2vec (Mikolov et al. 2013a)

Idea: achieve better performance allowing a simpler (shallower) model to be trained on much larger amounts of data

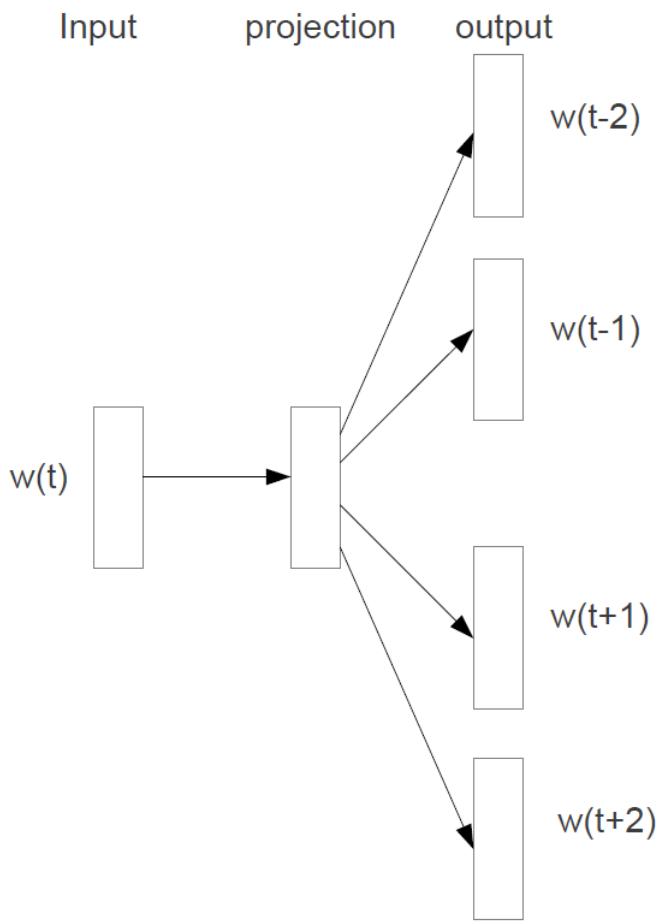
- No hidden layer (leads to 1000X speed up)
- Projection layer is shared (not just the weight matri
- Context contain words both from history and futu

«You shall know a word by the company it keeps»
John R. Firth, 1957:11.

…Pelé has called **Neymar** an excellent player…
…At the age of just 22 years, **Neymar** had scored 40 goals in 58 internationals…
…occasionally as an attacking midfielder, **Neymar** was called a true phenomenon…

These words will represent **Neymar**

Google word2vec Flavors

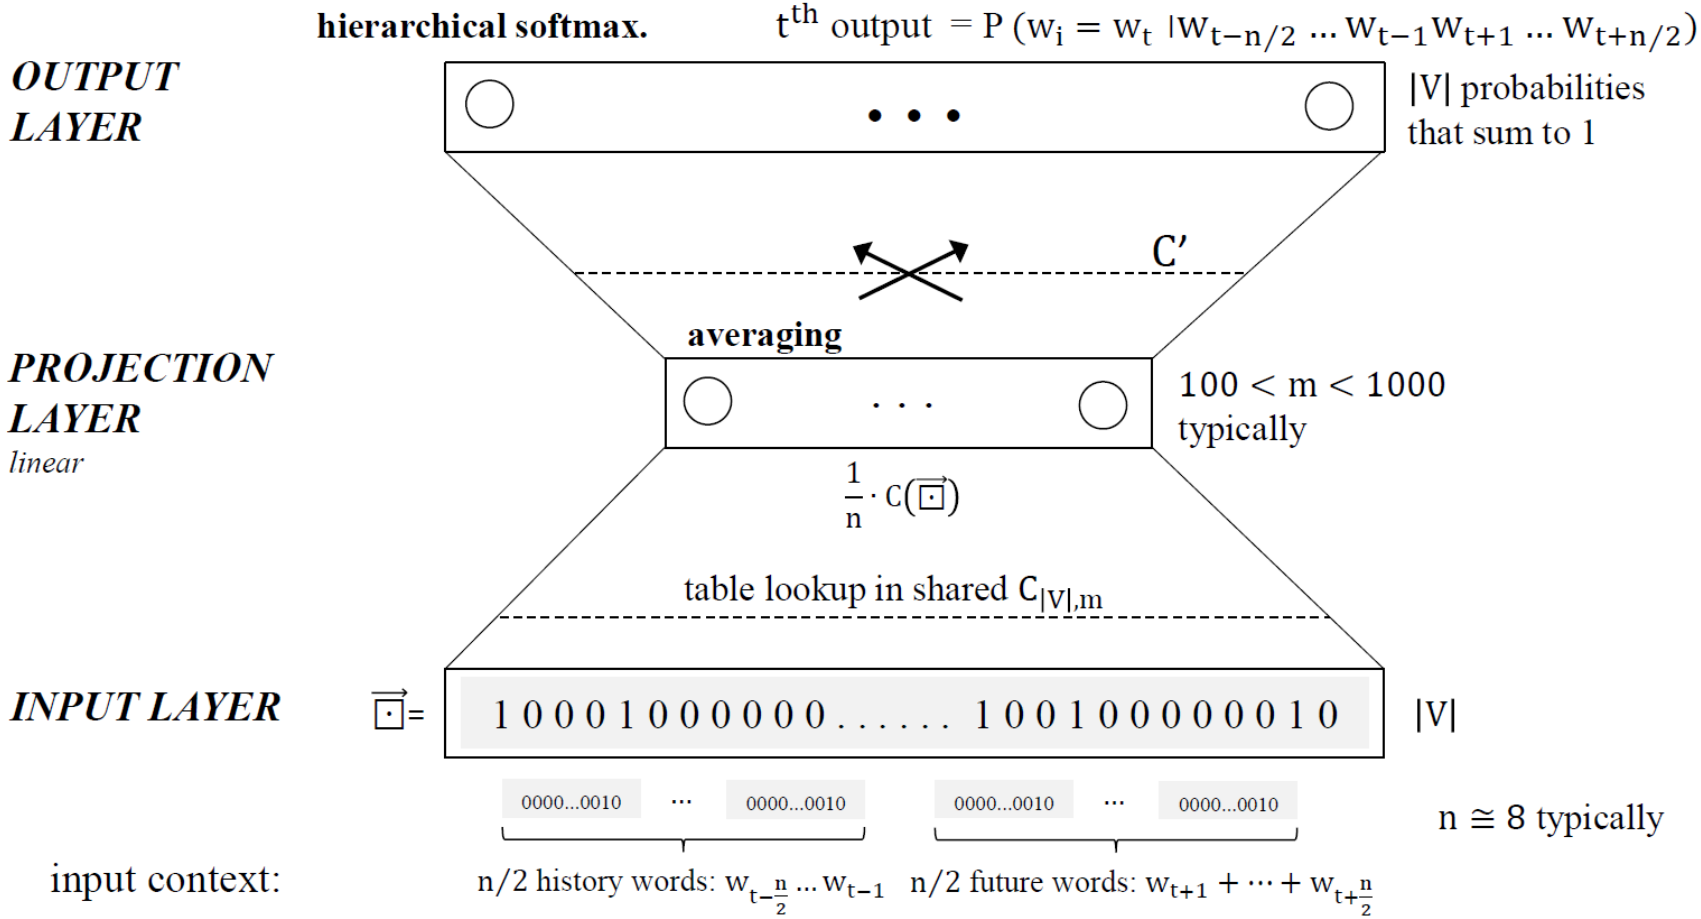


Skip-gram architecture

Word2vec's Continuous Bag-of-Words (CBOW)

For each training sequence: input = (context, target) pair: $(w_{t-\frac{n}{2}} \dots w_{t-1} w_{t+1} \dots w_{t+\frac{n}{2}}, w_t)$

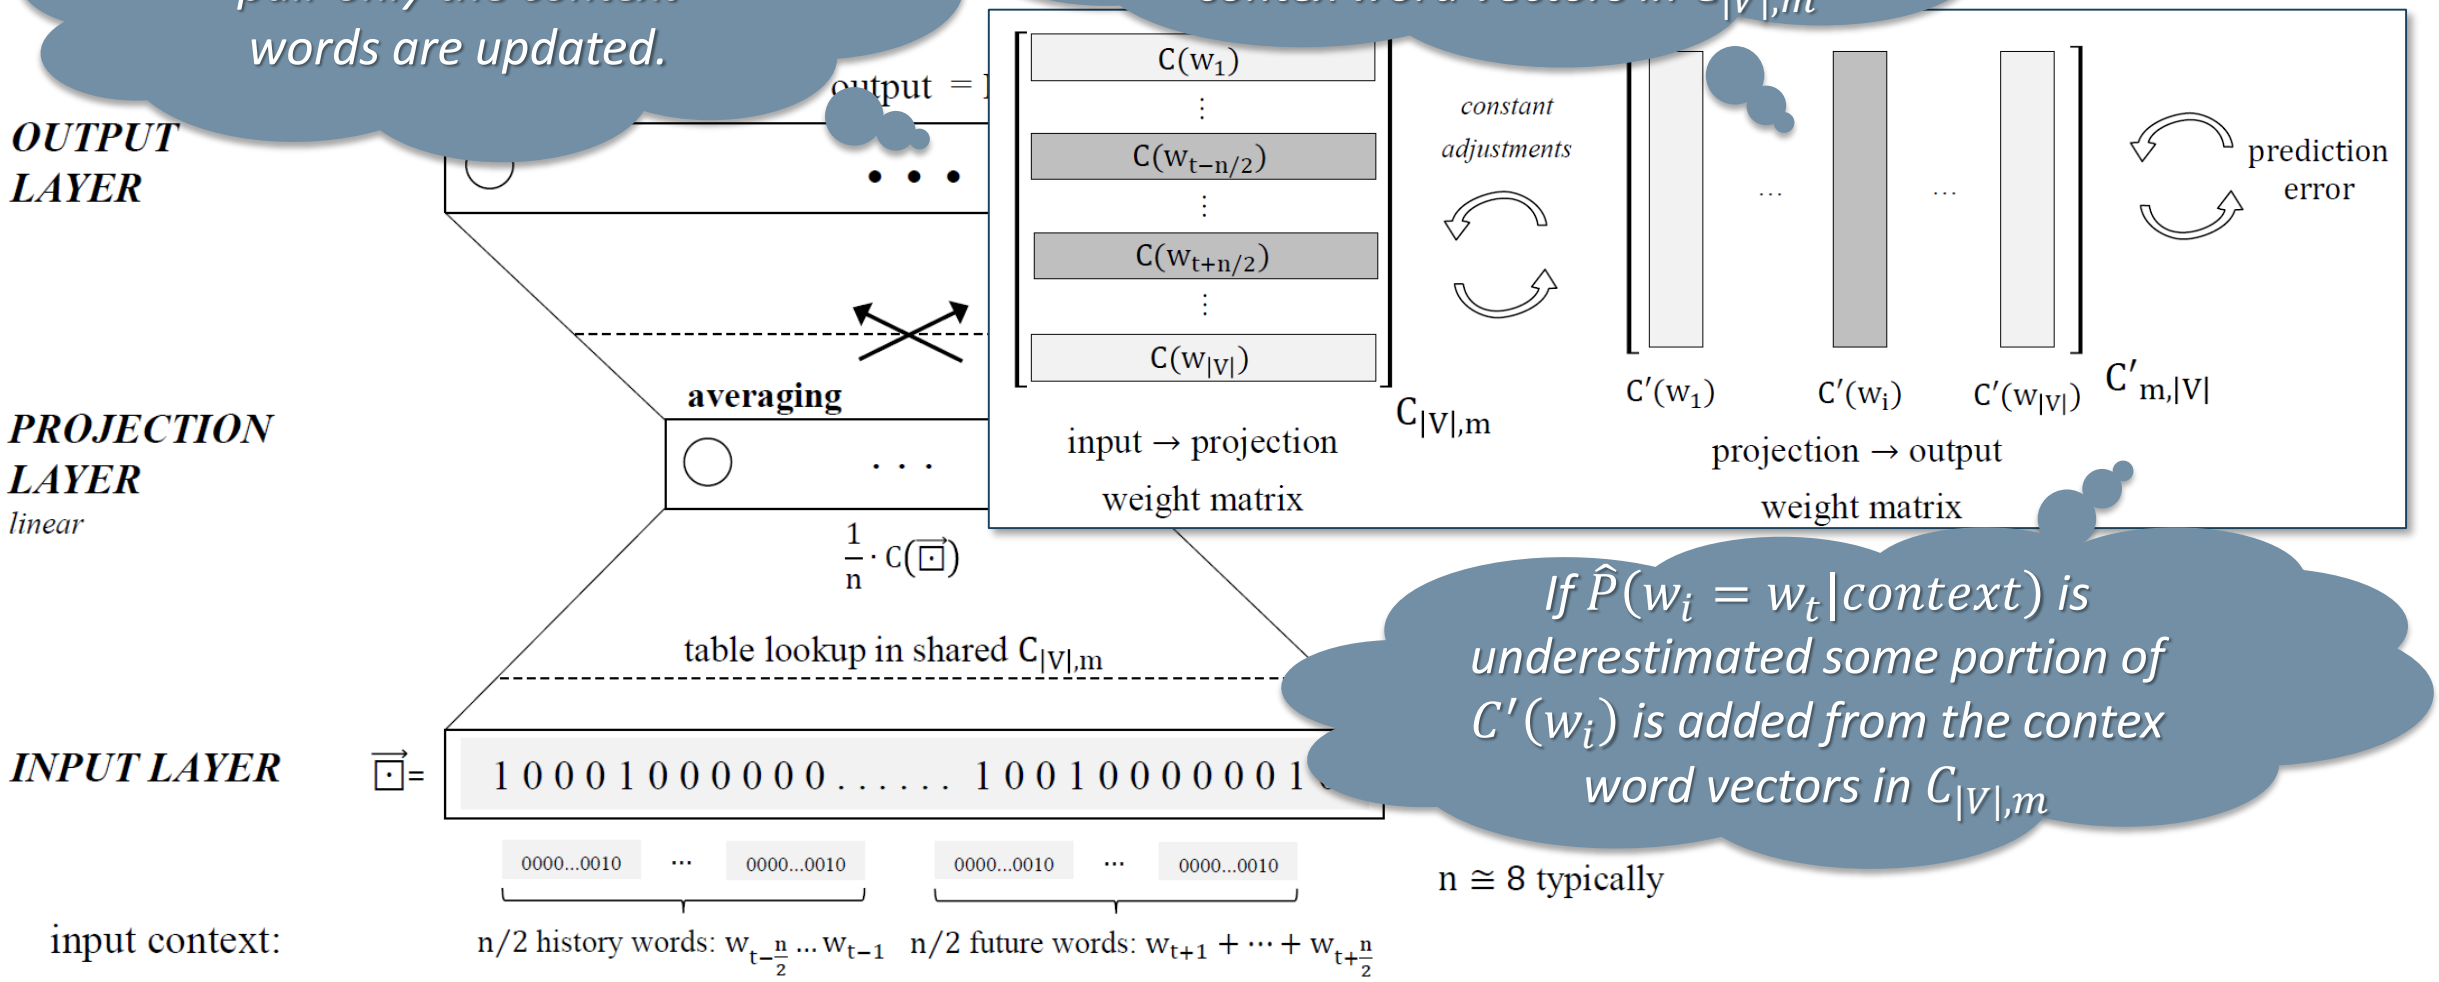
objective: minimize $E = -\log \hat{P}(w_t \mid w_{t-n/2} \dots w_{t-1} w_{t+1} \dots w_{t+n/2})$



Word2vec's Continuous Bag-of-Words (CBOW)

For each <context, target> pair only the context words are updated.

If $\hat{P}(w_i = w_t|context)$ is overestimated some portion of $C'(w_i)$ is subtracted from the contex word vectors in $C_{|V|,m}$



If $\hat{P}(w_i = w_t|context)$ is underestimated some portion of $C'(w_i)$ is added from the contex word vectors in $C_{|V|,m}$

Word2vec facts

Word2vec shows significant improvements w.r.t. the NNML

- Complexity is $n \times m + m \times log|V|$ (Mikolov et al. 2013a)
- On Google news 6B words training corpus, with $|V| \sim 10^6$
  - CBOW with m=1000 took 2 days to train on 140 cores
  - Skip-gram with m=1000 took 2.5 days on 125 cores
  - NNLM (Bengio et al. 2003) took 14 days on 180 cores, for m=100 only!
- word2vec training speed ≅ 100K-5M words/s
- Best NNLM: 12.3% overall accuracy vs. Word2vec (with Skip-gram): 53.3%

Capital-Country	Past tense	Superlative	Male-Female	Opposite
Athens: **Greece**	walking: **walked**	easy: **easiest**	brother: **sister**	ethical: **unethical**

Applications of word2vec in Information Retrieval

Example query: “restaurants in mountain view that are not very good”

Forming the phrases: “restaurants in (mountain view) that are (not very good)”

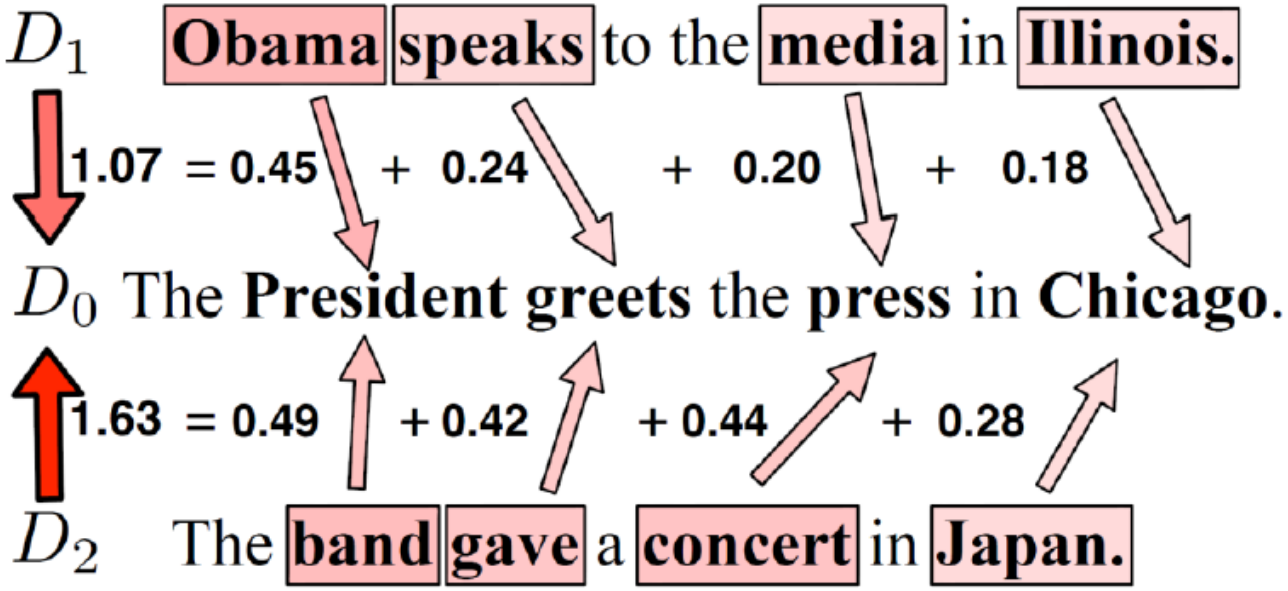
Adding the vectors: “restaurants + in + (mountain view) + that + are + (not very good)”

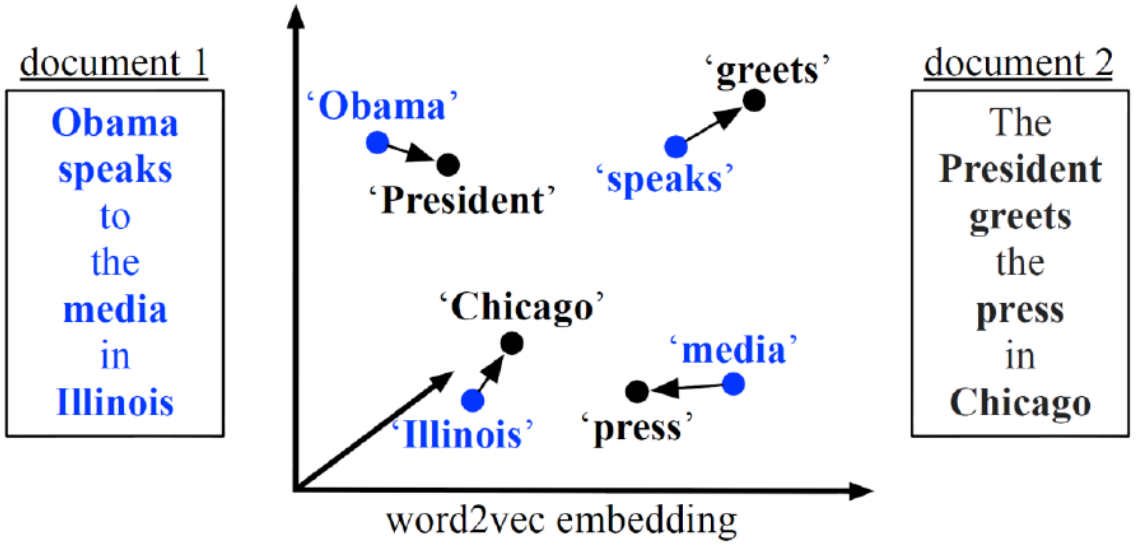
Expression	*Nearest tokens*
Czech + currency	koruna, Czech crown, Polish zloty, CTK
Vietnam + capital	Hanoi, Ho Chi Minh City, Viet Nam, Vietnamese
German + airlines	airline Lufthansa, carrier Lufthansa, flag carrier Lufthansa
Russian + river	Moscow, Volga River, upriver, Russia
French + actress	Juliette Binoche, Vanessa Paradis, Charlotte Gainsbourg

(Very simple and efficient, but will not work well for long sentences or documents)

Applications of word2vec in Document Classification/Similarity

With BoW D_1 and D_2 are equally similar to D_0.





Word embeddings allow to capture the «semantics» of the document ...

Applications of word2vec in Sentiment Analysis

«You shall know a word by the company it keeps»
John R. Firth, 1957:11.

No need for classifiers, just use cosine distances …
